### Introduction

Current bacterial models are built from gene annotations, where gene function is deduced through homology-based algorithms and software, such as RAST (Rapid Annotation using Subsystem Technology)

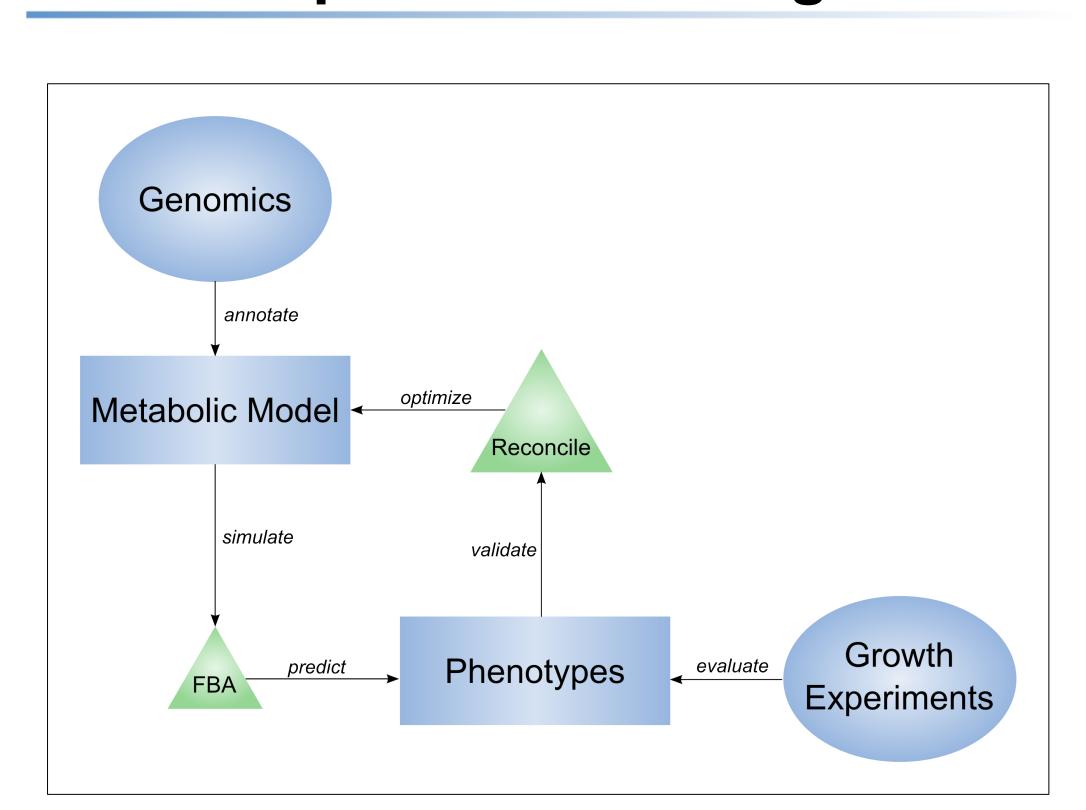

Novel functional roles are left undiscovered when they cannot be extrapolated from current annotation software

Using flux-balance analysis (**FBA**) software, metabolic models can be used for *in silico* prediction of growth rates and biomass yield upon a variety of growth conditions

Recent developments using phenotype microarrays (**PMs**) provide a high-throughput, large-scale technique for profiling bacterial phenotypes upon a variety of growth conditions

*Citrobacter sedlakii* genome was sequenced using next-gen sequencing and assayed on PMs

Coupling PM experiments with FBA software, metabolic models can be reconciled and optimized to best predict bacteria response and yield

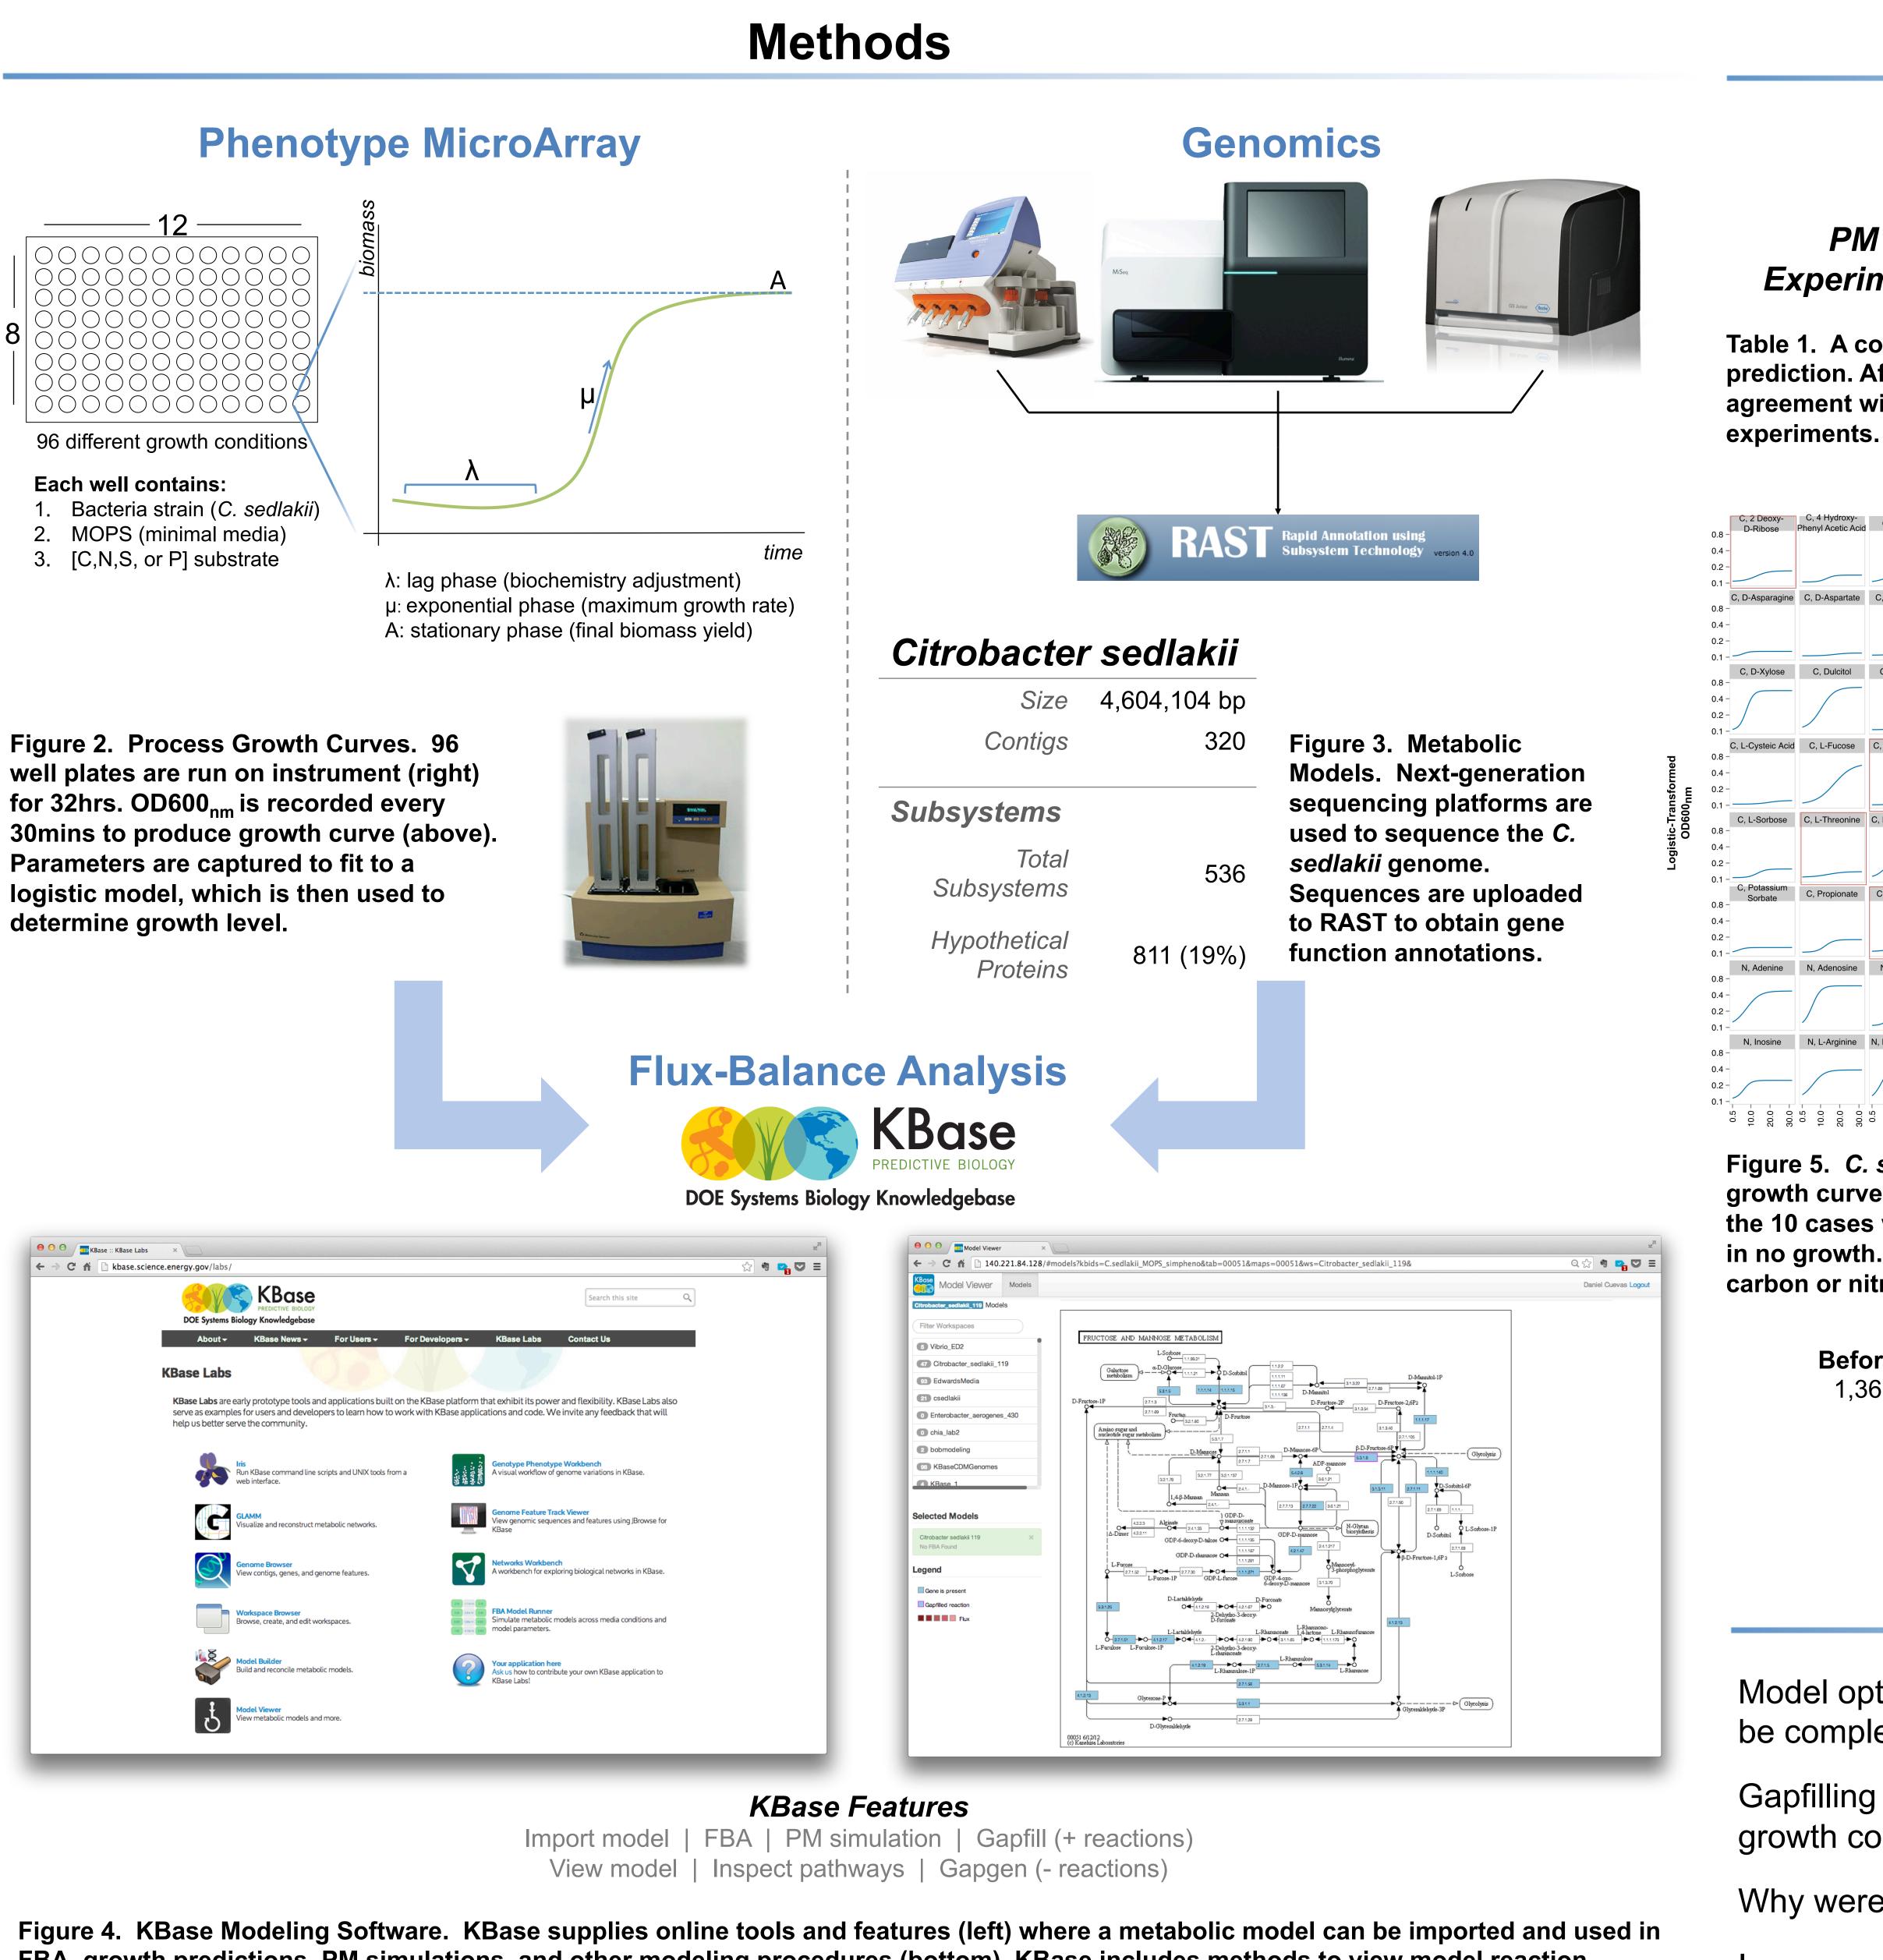

### **Experimental Design**

Figure 1. Analysis Overview. Combine genomics and phenomics in order to create, test, and reconcile bacteria metabolic models.

# High-throughput phenotype profiling for bacterial flux-balance model optimization

Figure 5. *C. sedlakii* Growth Curves. A logistic model is fitted to the growth curve to extract phenotype parameters. Red boxes highlight the 10 cases where FBA predicted growth and PM modeling resulted in no growth. The letter preceding the substrate name identifies it as a carbon or nitrogen source.

> **Before Gapfilling** 1,367 reactions

strains

After Gapfilling 1,399 reactions

32 reactions total added to model 13 out of 32 are metabolite transporters 12 existing reactions made reversible

### Conclusion

- Model optimization for over 90 growth conditions can be completed quickly
- Gapfilling still requires manual execution (run for each growth condition)
- Why were these genes missing from model?
- Increase number of growth conditions and bacteria
